The following description includes information that may be useful in understanding the present invention. It is not an admission that any of the information provided herein is prior art or relevant to the presently claimed invention, or that any publication specifically or implicitly referenced is prior art. Approximately 40% of the adult population in the United States has hypertension, with the majority of cases diagnosed in the early stages. Treatment of hypertension includes a combination of drugs and lifestyle modifications. Patients diagnosed with hypertension are generally prescribed a combination of drugs to manage the disease. Often, side effects and adverse drug reactions can discourage patients from taking their prescribed medication. Thus, there is a need for new approaches to hypertension management, which reduce the side effects and improve the effectiveness of existing treatments. It is well established that dietary salt and water intake, directly correlate with the development of cardiovascular diseases and are important factors in the development of hypertension. Lowering salt intake and correcting the imbalance of sodium (salt) and potassium (a necessary nutrient to maintain the ability of the cell to function normally) can help prevent or reduce hypertension. Existing blood pressure measuring devices are often difficult to operate and monitor. Thus, patients often rely on advice and feedback from their doctors to track and monitor their blood pressure. Patients also often lack the time and resources to track and monitor their blood pressure at regular intervals. Accordingly, there is a need for effective techniques and apparatuses to facilitate the measurement, tracking and/or monitoring of blood pressure. Hypertension is a condition that can be tracked with blood pressure measurements taken over a period of time. Traditionally, blood pressure is measured in the doctor's office or clinic, usually with a sphygmomanometer, an expensive instrument that requires specialized training to operate and interpret the results. Recently, there has been a growing interest in the use of portable blood pressure monitors. Such devices are a lower cost alternative to sphygmomanometers and are used to measure blood pressure during daily activities. These devices are typically smaller than the traditional sphygmomanometers, and can be operated by patients or caregivers themselves, without
